

all ImageSegmentation.java methods applied to a few pairs of images that are panoramic sets or stereo image sets with the goal of finding best segmentation for finding blobs to make matchable contours.

summary of next pages:

for brown & lowe 2003, best was KMPP w/ k=2

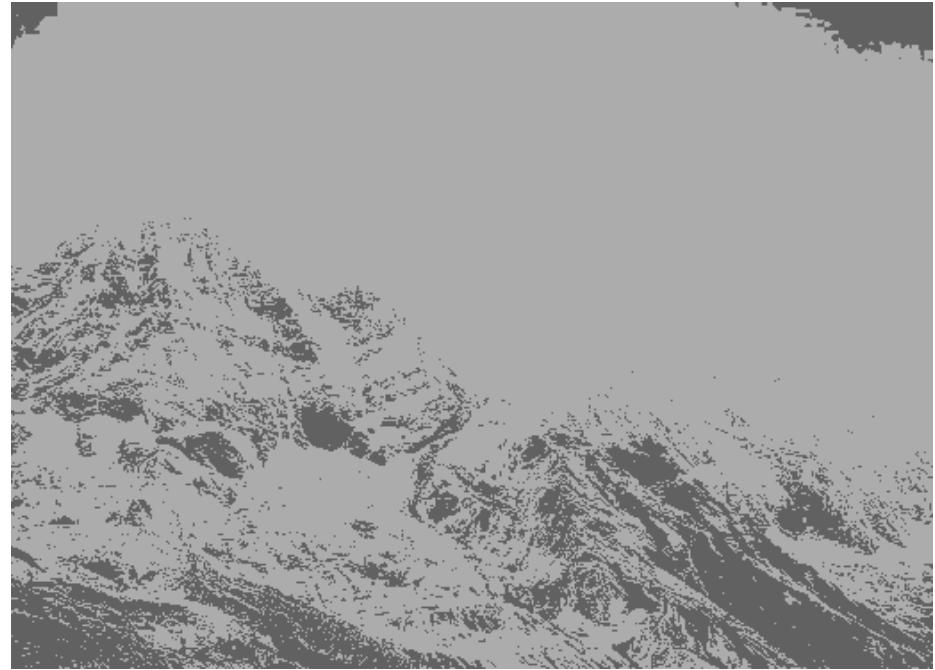

for Venturi, best was PolarCIEXYAndFrequency

for books, best was KMPP w/ k=2, 3 or 8

Venturi has lots of texture, so attempting a low resolution segmentation first is faster (the polar ciexy and frequency segmentation is $O(N)$... check that).

Books best matchable features w/o illumination and projection differences are the text. The text needs further processing such as adaptive mean thresholding.

part of green droid is lost in grass watershed

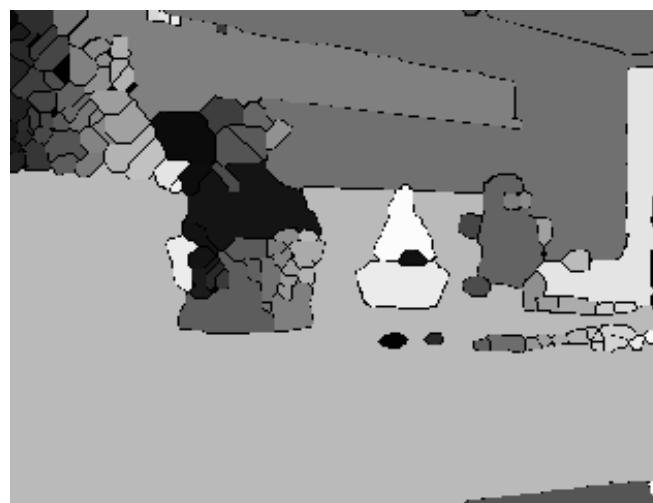

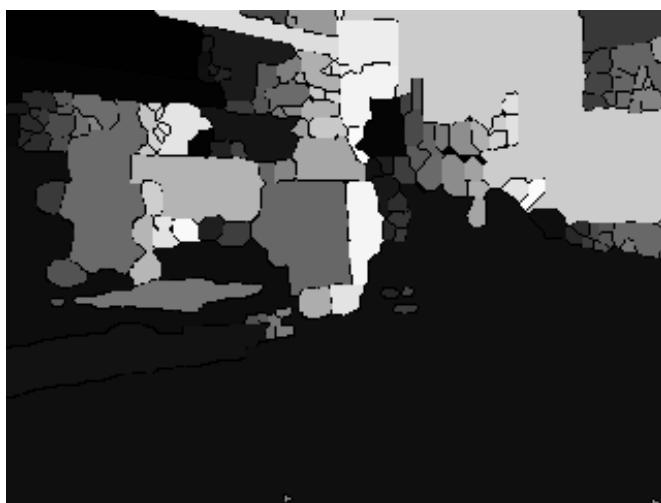

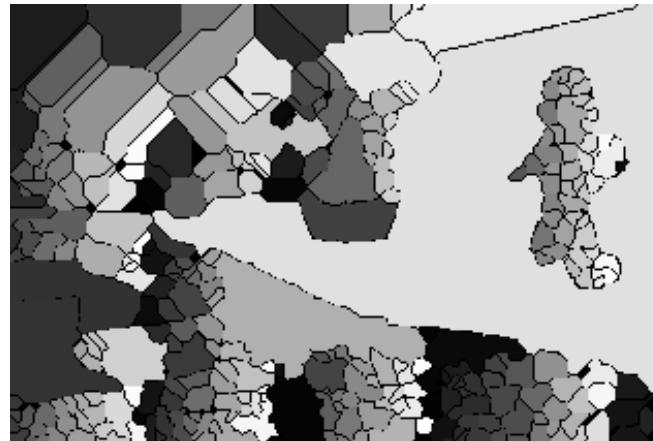

O2 watershed:

O2 watershed:

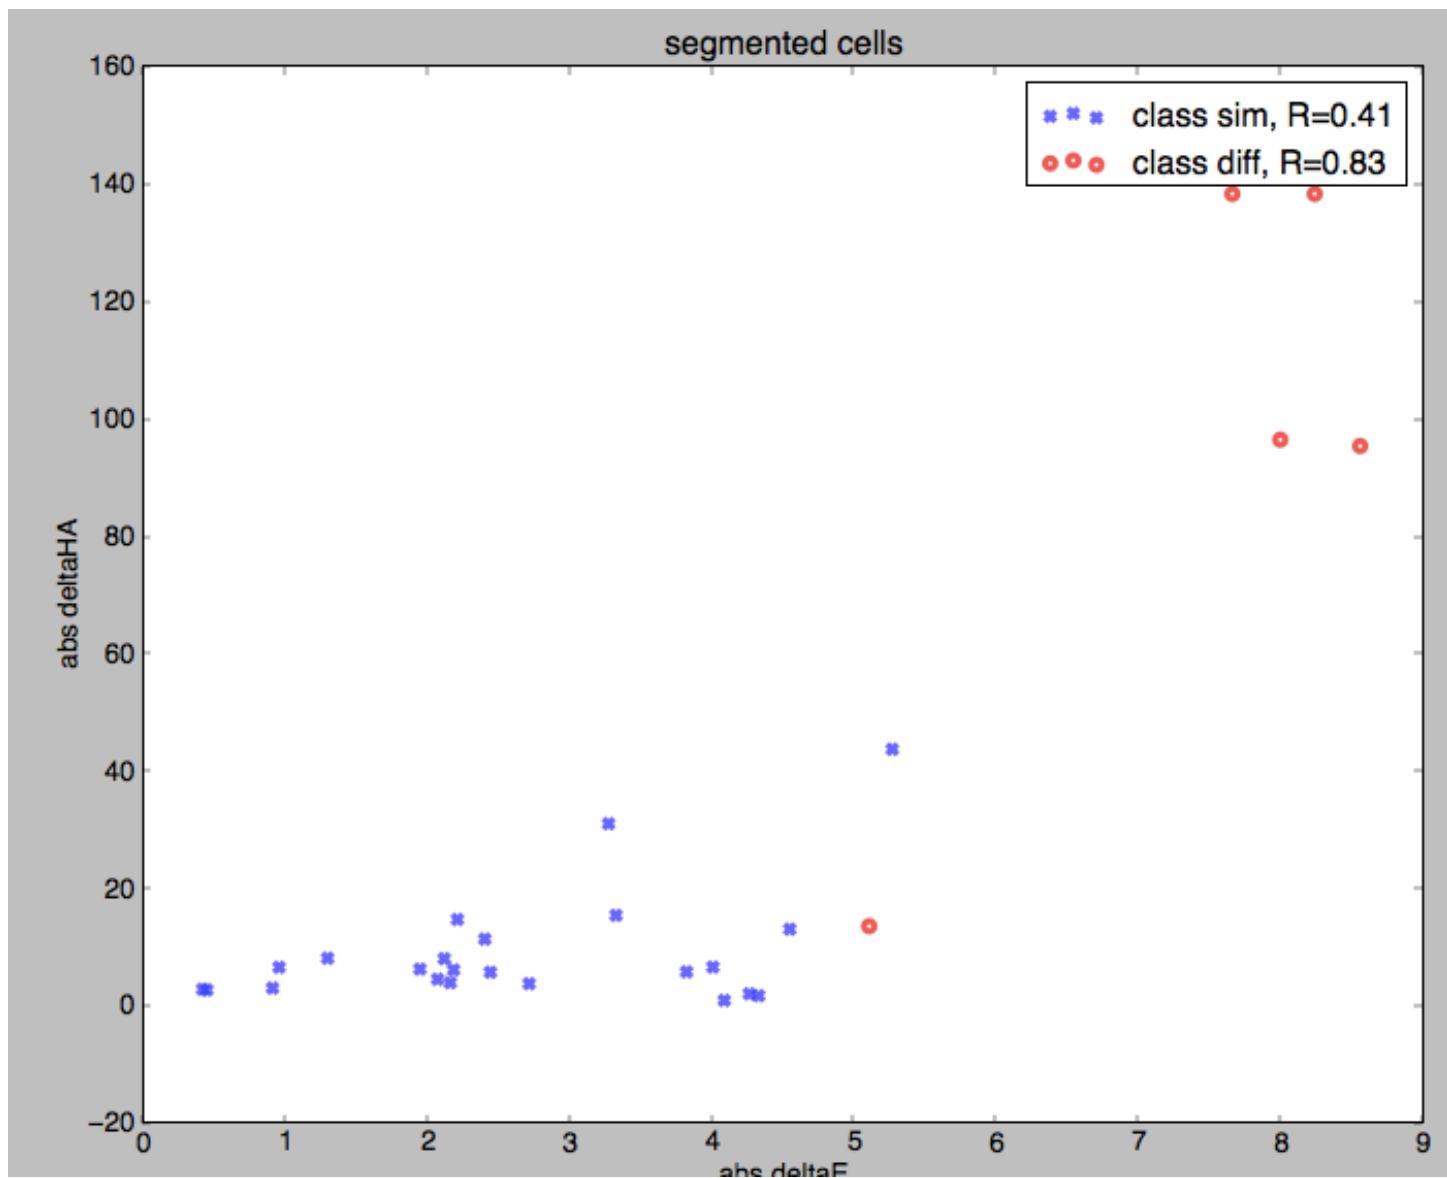

have created an image to use watershed algorithm on as the start of a color segmentation algorithm. A greyscale image is created and a small sigma first derivative gaussian is applied to the image. Thresholding for a fraction of the number of counts is performed to remove the lowest intensity pixels, then the image is inverted and combined with an image that is the O1 adaptive median image. A watershed algorithm is performed on that combined image to give the following results. The results are very granular, so an algorithm to merge similar adjacent cells has been made too.

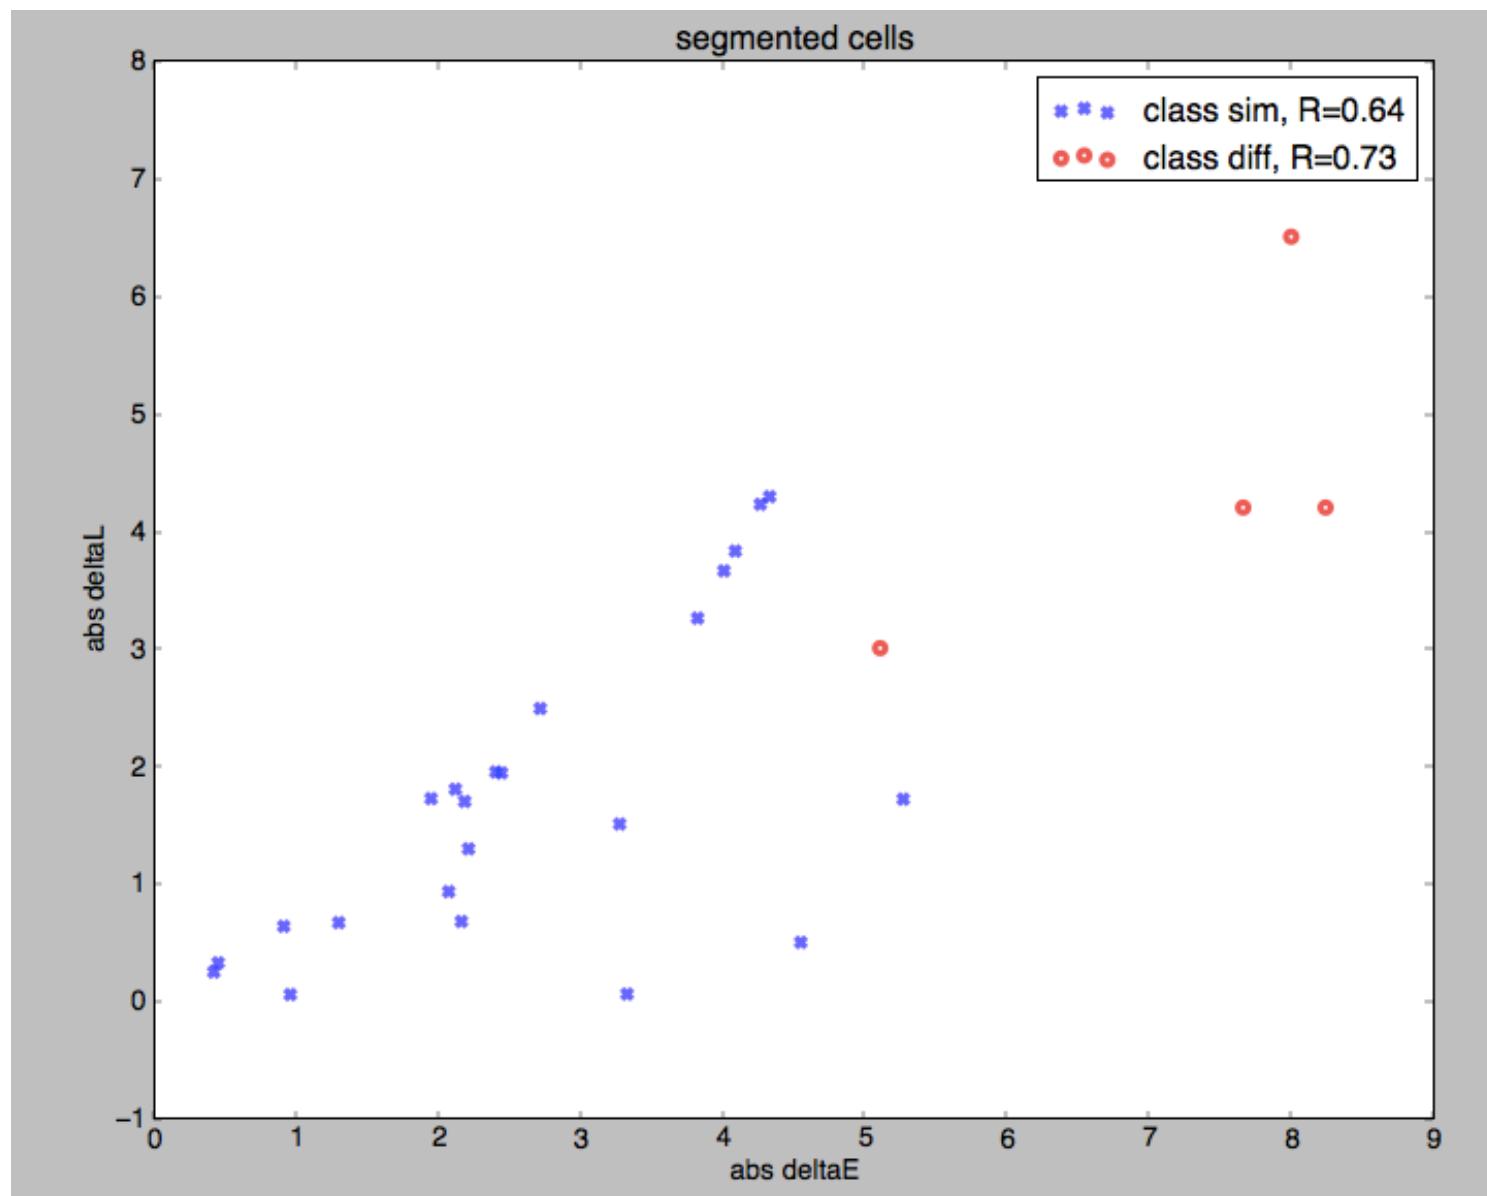

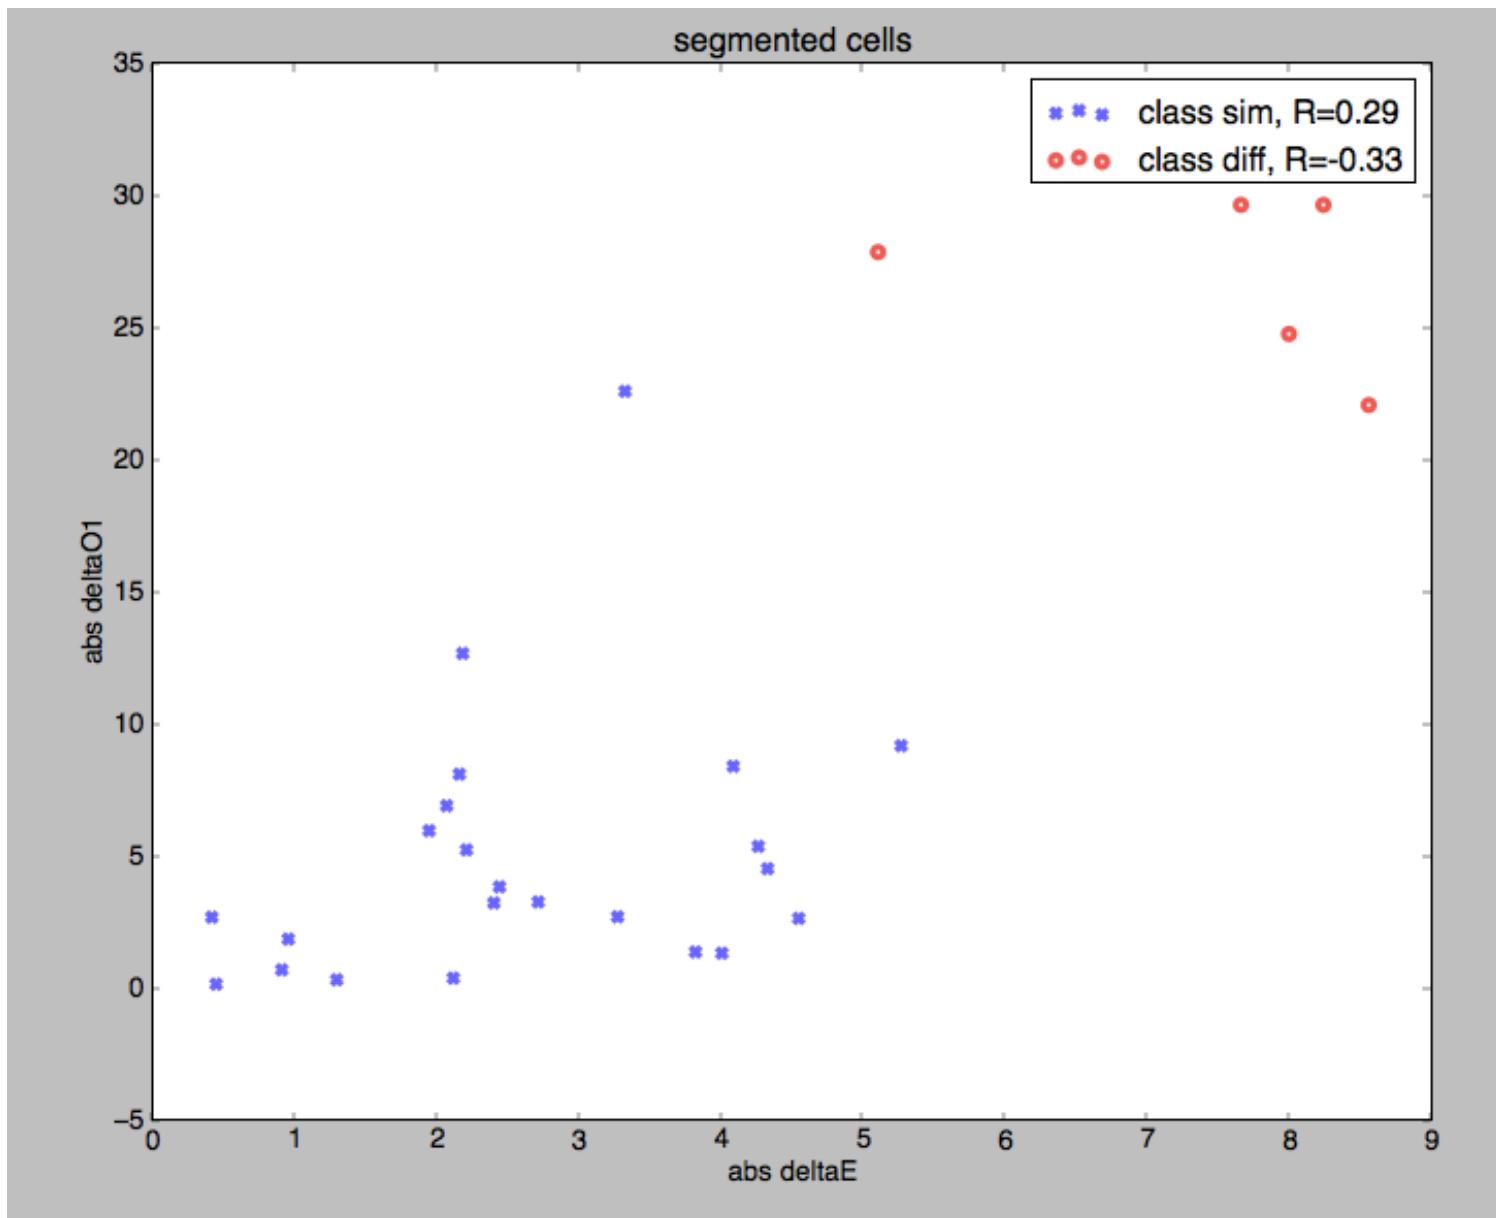

A file of similar and different pairs of adjacent cells and their colors was made as 2 'classes' for LDA of the colors to find the best combination of colors for separating the classes.

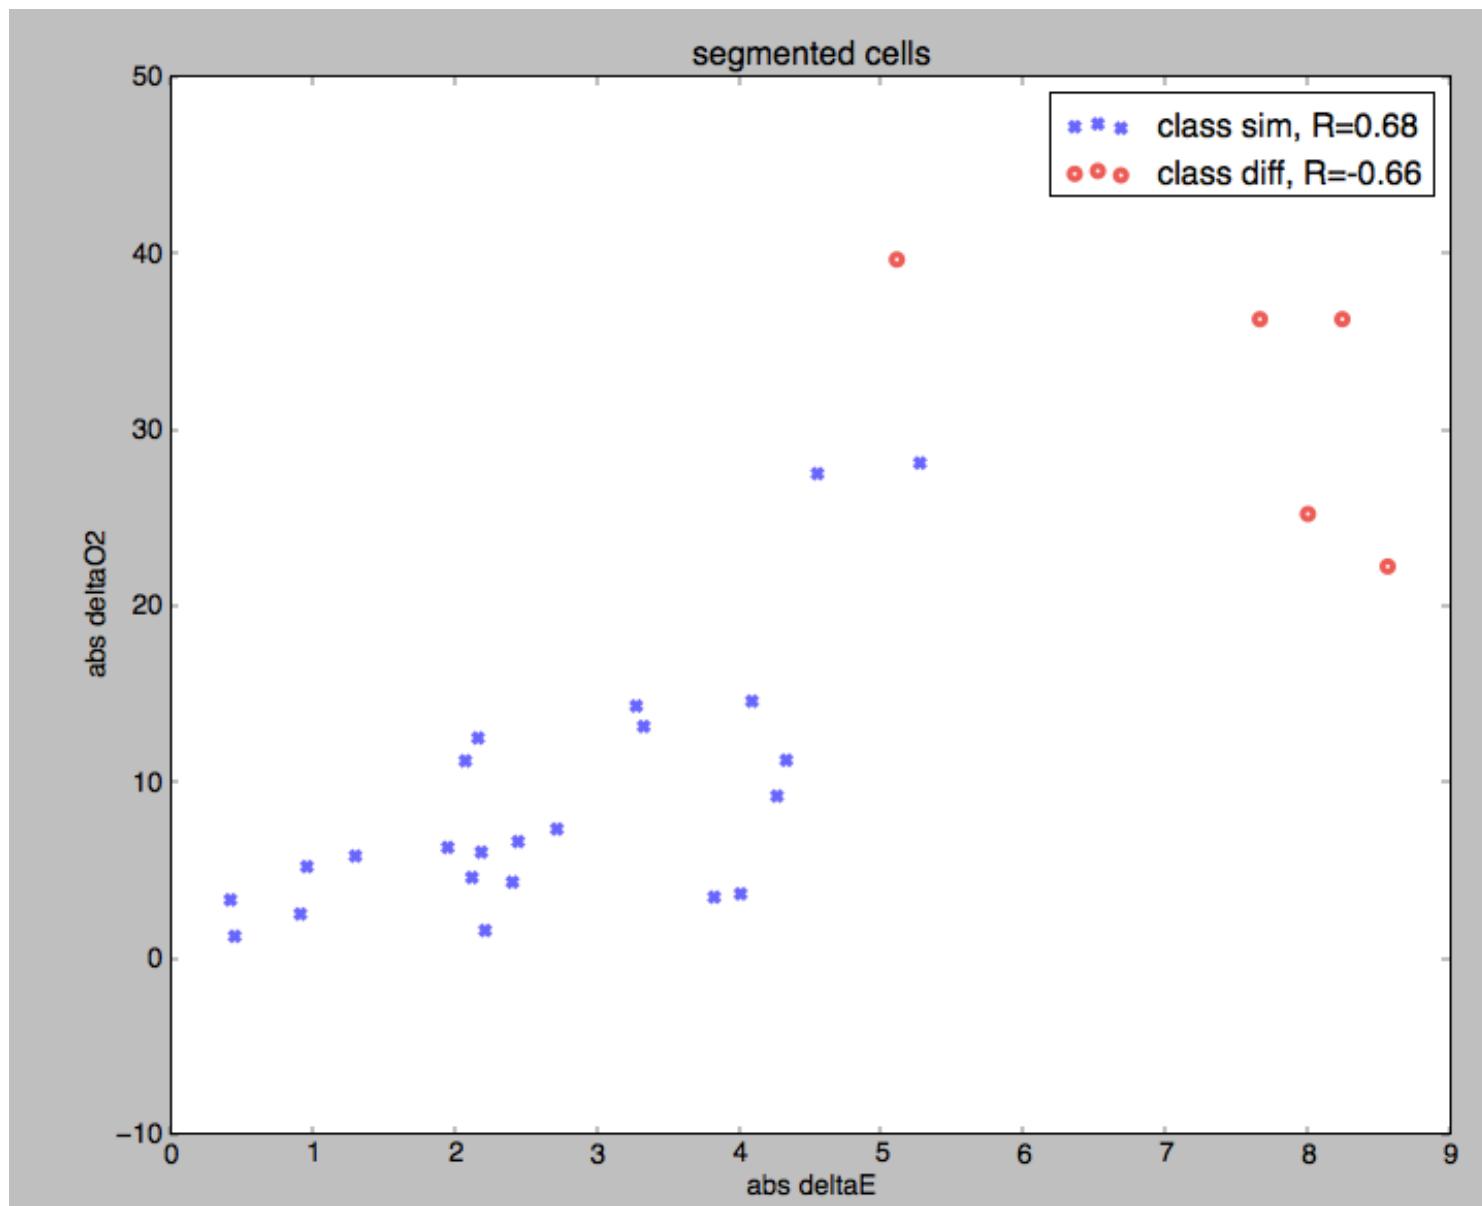

The best results were to use deltaE 1994 and delta opponent colors.

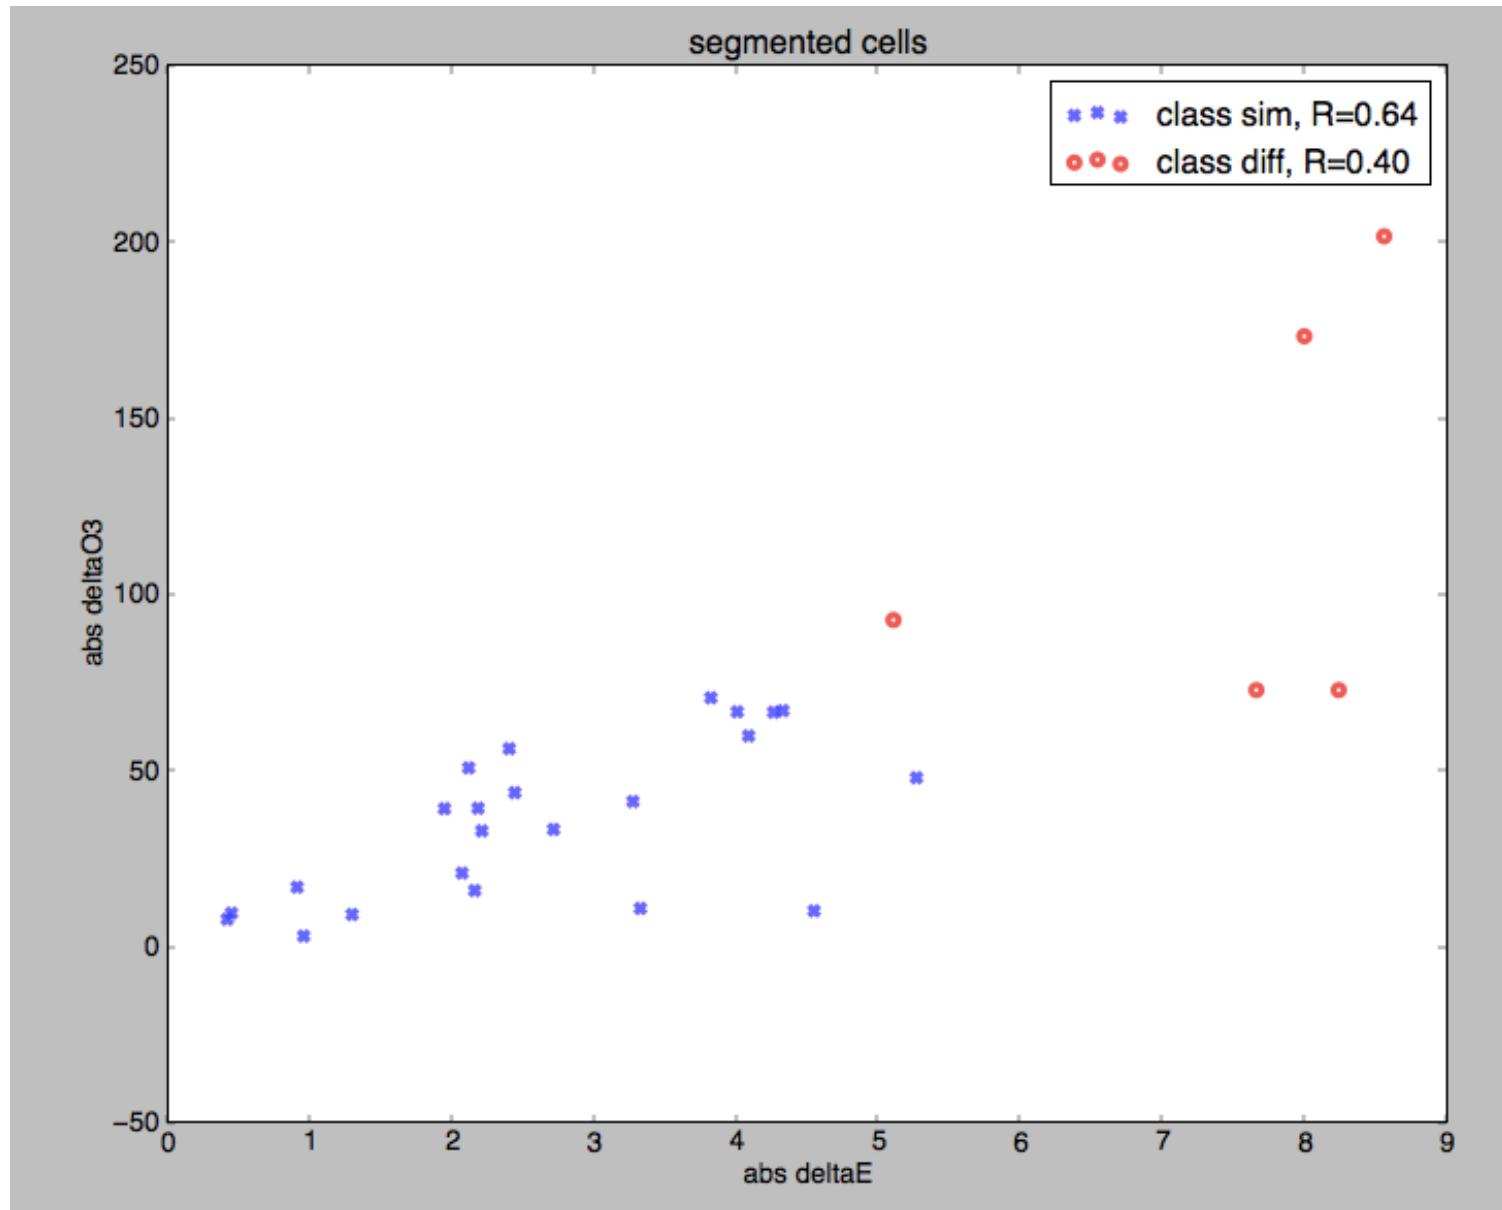

The next pages are diagrams of the results.

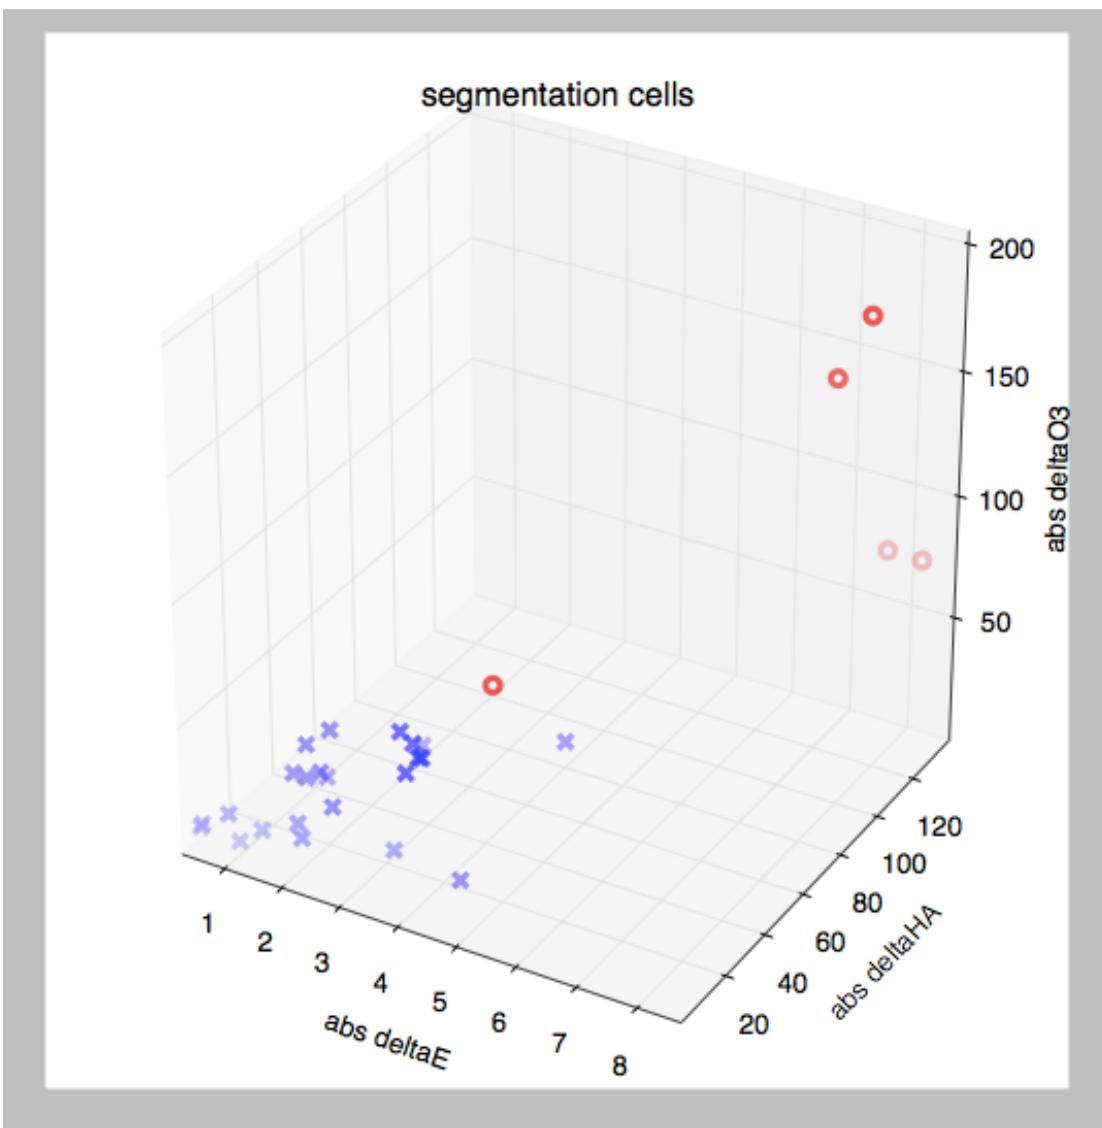

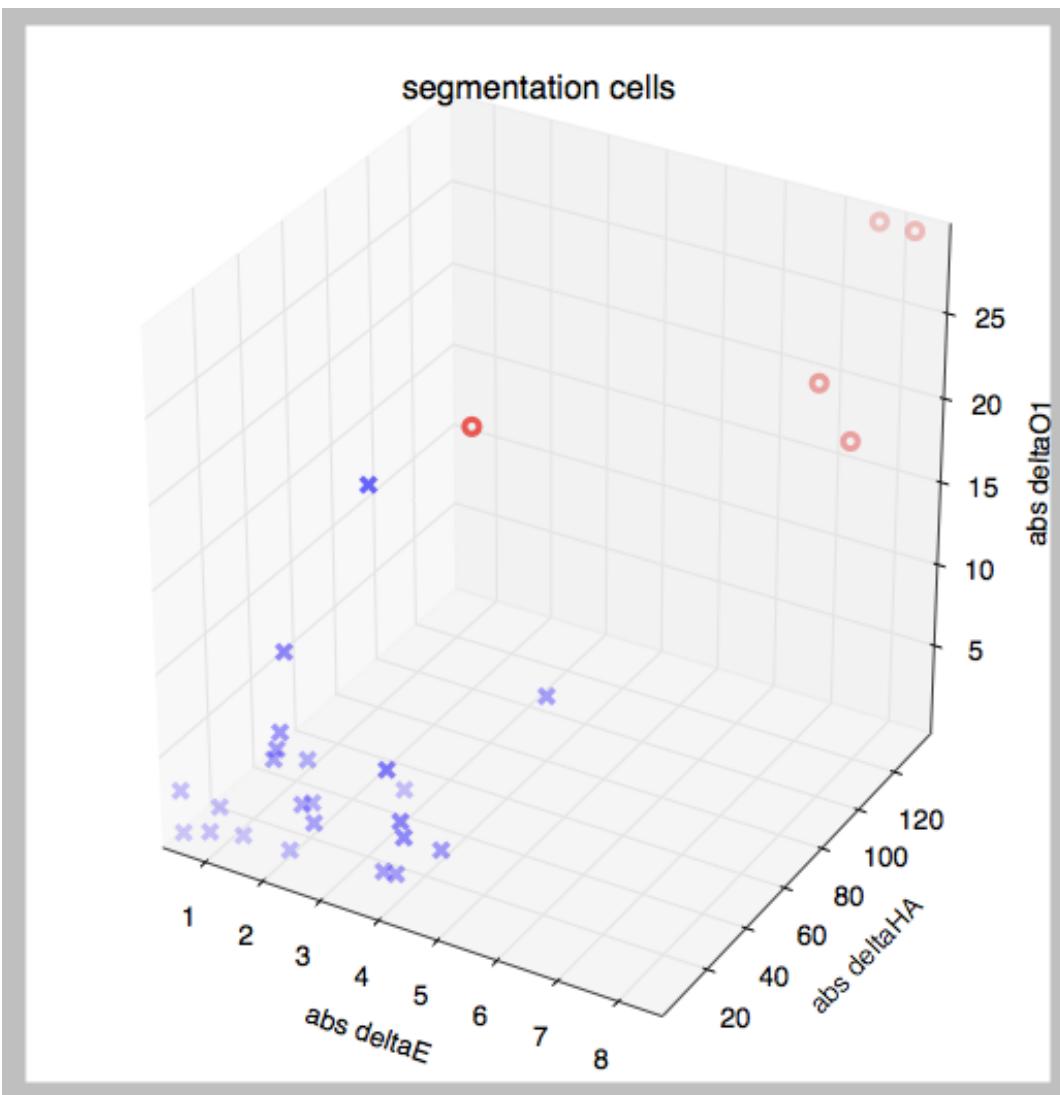

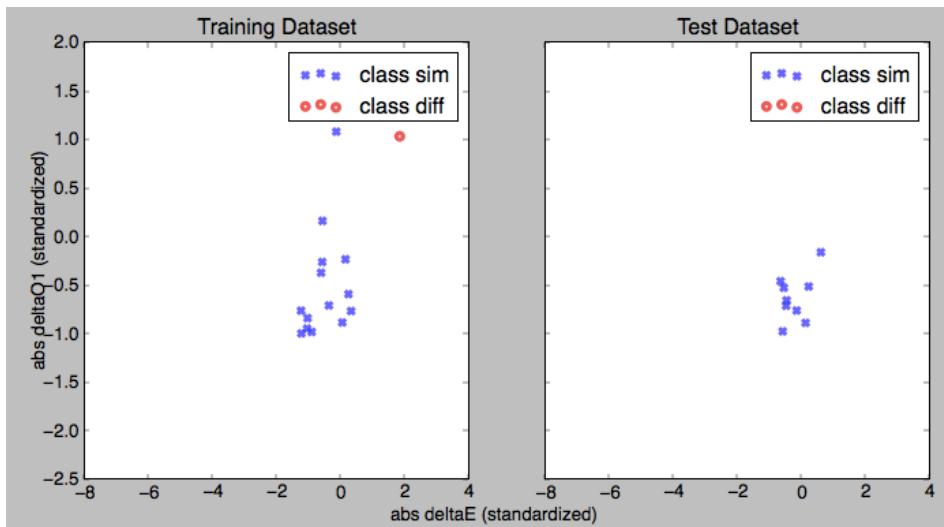

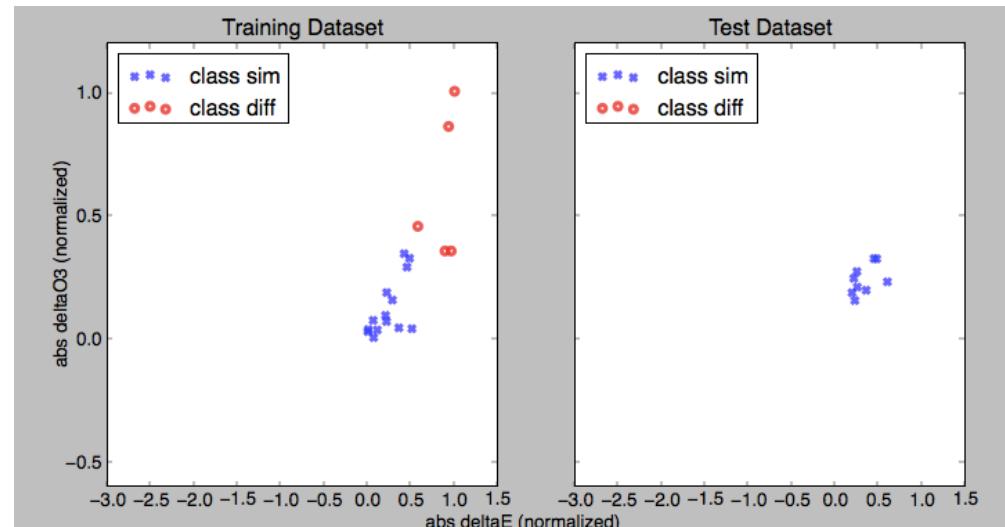

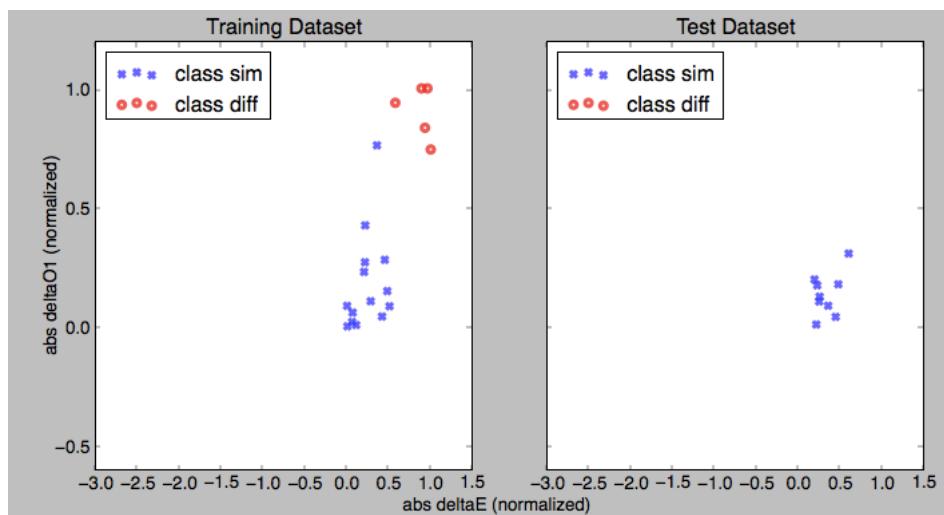

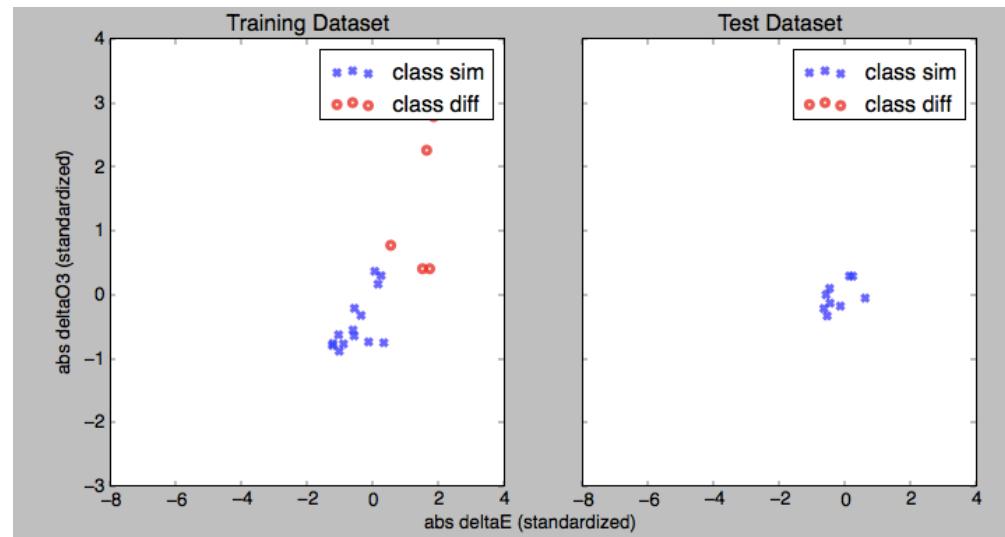

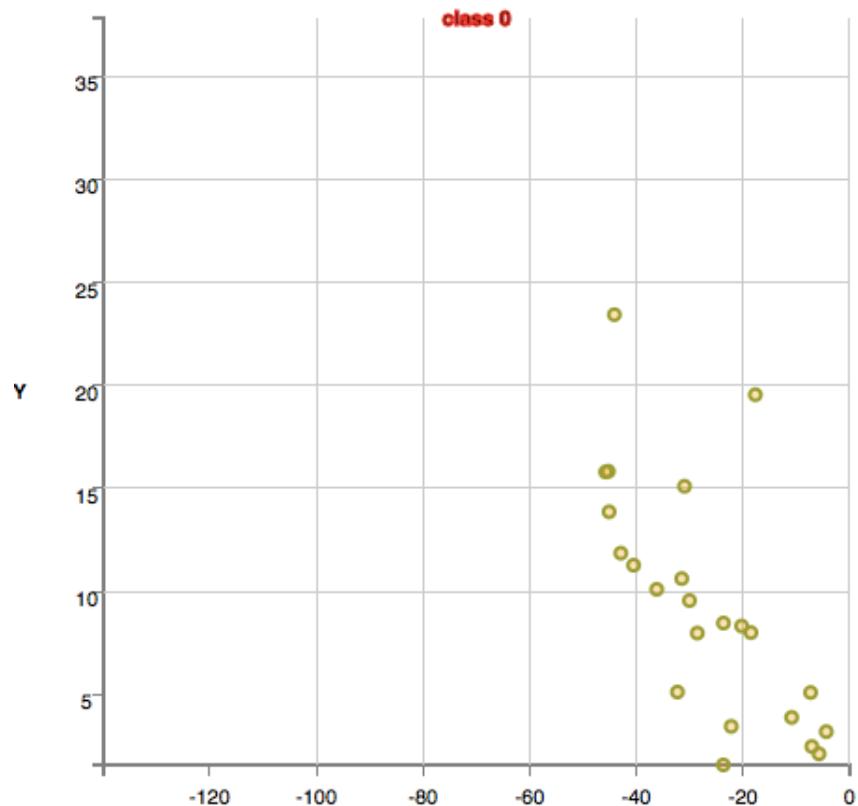

deltaE and delta O1

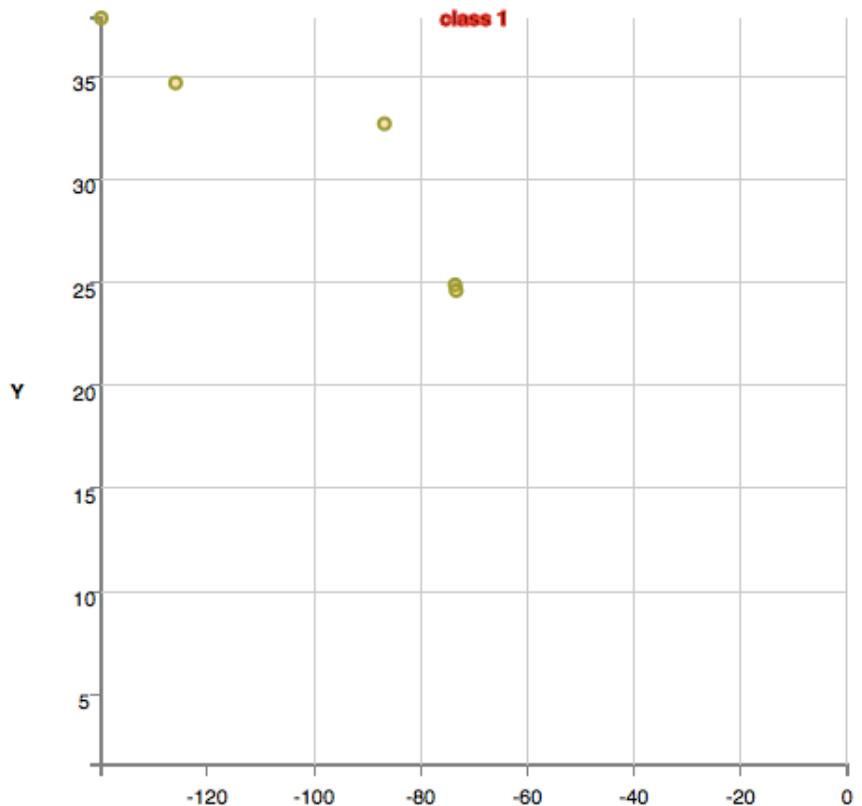

deltaE and delta O3

similar cells

different cells

result of LDA applied to feature classes using deltaE 1994, delta O1, delta O2, and delta O3.

(more points will be used when adjacency map is improved).
